P8160 Simulation Project - Hierarchical Logistic Model for Mulitcenter Clinical Trial

Group 3A: Kate Colvin, Xuanyu Guo, Dang Lin, and Boxiang Tang

Introduction and Background

A multicenter clinical trial is a trial that enrolls participants at multiple different medical institutions. While there are a number of distinct advantages to multicenter trials, such as the possibilities for a larger sample size and greater generalizability [Jo, 2020], they are also expensive and more complex to execute and analyze. For instance, different trial sites can have different characteristics, such as patient demographics, treatment practices, or geographic factors, that impact the outcome of trial patients. Such variability between trial sites can complicate the statistical analysis, and possibly bias trial outcomes. Moreover, in some cases, multicenter clinical trials have contradicted single-center trials [Dechartres, 2011]. Therefore an important goal of statistical clinical trial research must be to create methods and guidelines for the reliable design and analysis of multicenter clinical trials.

A challenge in evaluating clinical trial methodology is the cost of conducting a trial and the accessibility of this data to external researchers. It's been long recognized that simulation studies can play a key role in designing and analyzing clinical trials by improving their efficiency and reliability [Bonate, 2000]

In this project, we designed a simulation study to determine optimal Monte Carlo sampling strategies to evaluate the population-level probability of adverse events in the context of a hypothetical multicenter clinical trial. This simulated trial includes patient-level covariates and clinic-level random effects that informs a heirarchical logistic model to predict the probability of adverse events. We evaluated the bias and variance in the predicted probability of an adverse event of three sampling methods: simple Monte Carlo (MC), MC with control variates (CV), and MC with importance sampling (IS). We also compare the CPU time statistics for each method.

Statistical Methods

In order to evaluate our different Monte Carlo sampling stratgies, we created a synthetic data set meant to represent a hypothetical multicenter clinical trial. This data set includes patient-level covariates X_i and clinic-level random effects b_j , which represents site-specific variables such as population demographics and differences in protocol. We specified the clinic random effect as $b_j \sim INSERT\ DIST\ AND\ PARAMETERS$ HERE lol and the patient level covariates as $X_i \sim INSERT\ DIST\ AND\ PARAMETERS\ HERE\ lol$.

These random variables are used to estimate the population-level probability of an adverse event using the logit function below:

test

Statistics of interest: We are interested in estimating the overall (population-level) probability of an adverse event, marginalizing over both X (across all patients) and the random effect distribution b (across all clinics): overall description of what we did, the code in this section specifies functions

1. Initialization and Function Definitions

We specified the clinic random effect (b) as $b \sim t_5$ and the patient-level covariates (X) as $X \sim \text{Gamma}(2, 1)$.

```
# logistic function
logistic <- function(z) {</pre>
  1 / (1 + \exp(-z))
}
# Set model parameters
alpha <- 0 # Intercept
                 # Covariate coefficient
beta <- 1
# Define random generators for non-normal distributions
                   of random effect b and covariate x
# Example: b \sim t_5 (heavy-tailed distribution)
r_b <- function(n) {</pre>
 rt(n, df = 5)
# Example: x ~ Gamma(shape=2, rate=1)
r_x <- function(n) {</pre>
 rgamma(n, shape = 2, rate = 1)
```

2. Sampling from Simple Monte Carlo (MC)

```
simpleMC <- function(N) {
    # Sample b from f(b)
    b_samp <- r_b(N)
    # Sample x from f(x)
    x_samp <- r_x(N)

# Compute p_i = logistic(alpha + b_i + beta*x_i)
    p_values <- logistic(alpha + b_samp + beta * x_samp)

# Simple MC estimate is the average of p_values
    est <- mean(p_values)

return(list(est = est))
}</pre>
```

3. Designing Control Variate (CV)

```
# 3.1 Define a control variate g(b, x)
#    It should be correlated with the target function but have a known or easily
#    approximated expectation. As an example, we use a probit-based function.

g_function <- function(b, x) {
    # Example: replace logistic with pnorm (probit)
    z <- alpha + 0.8 * b + 0.8 * x # 0.8 is a heuristic factor here
    return(pnorm(z))
}

# 3.2 Approximate E[g] using a large-scale MC, since we might not have a closed-form
approx_Eg <- function(N = 5e5) {
    b_samp <- r_b(N)</pre>
```

```
x_{samp} \leftarrow r_x(N)
  mean(g_function(b_samp, x_samp))
# 3.3 Control variate MC estimate
cvMC <- function(N, Eg_true = NULL) {</pre>
  if(is.null(Eg_true)) {
    # If not provided, approximate E[g] with a bigger MC sample
    Eg\_true \leftarrow approx\_Eg(N = 5e5)
  # Sample from original distributions
  b_{samp} \leftarrow r_b(N)
  x_{samp} \leftarrow r_x(N)
  # Target function p(b,x)
  p_vals <- logistic(alpha + b_samp + beta * x_samp)</pre>
  # Control variate q(b,x)
  g_vals <- g_function(b_samp, x_samp)</pre>
  # (1) Simple estimates of p and g
  p_mean <- mean(p_vals)</pre>
  g_mean <- mean(g_vals)</pre>
  # (2) Optimal gamma via covariance
  cov_pg <- cov(p_vals, g_vals)</pre>
  var_g <- var(g_vals)</pre>
  gamma_opt <- cov_pg / var_g</pre>
  # (3) Construct CV estimator
 p_cv <- p_mean - gamma_opt * (g_mean - Eg_true)</pre>
  # This returns the CV estimate, gamma, and other useful metrics
  return(list(est = p_cv))
```

4. Importance Sampling (IS)

```
# 4.1 Define the auxiliary distribution h(b,x)
# Here we show an example of independent sampling from h(b)*h(x).
# We'll pick t_3 for b (heavier tail) and tweak Gamma parameters for x.

# b ~ t_3
r_b_IS <- function(n) {
    rt(n, df = 3)}
}
# PDF of b for t_3
d_b_IS <- function(b) {
    dt(b, df = 3)}

# x ~ Gamma(shape=2, rate=0.5)
r_x_IS <- function(n) {
    rgamma(n, shape = 2, rate = 0.5)</pre>
```

```
}
# PDF of x for Gamma(shape=2, rate=0.5)
d_x_IS <- function(x) {</pre>
  dgamma(x, shape = 2, rate = 0.5)
# 4.2 Implement Importance Sampling
IS MC <- function(N) {</pre>
  # Sample from h(b,x)
  b_samp <- r_b_IS(N)</pre>
  x_{samp} \leftarrow r_x_{IS}(N)
  # Compute original PDF values f(b), f(x)
  fb_vals \leftarrow dt(b_samp, df = 5) # original t_5 for b
  fx_vals <- dgamma(x_samp, shape = 2, rate = 1) # original Gamma for x
  # Compute auxiliary PDF values h(b), h(x)
  hb_vals <- d_b_IS(b_samp)</pre>
  hx_vals <- d_x_IS(x_samp)</pre>
  # Weights w_i = [f(b_i)*f(x_i)] / [h(b_i)*h(x_i)]
  w <- (fb_vals * fx_vals) / (hb_vals * hx_vals)</pre>
  # Target function p(b,x)
  p_vals <- logistic(alpha + b_samp + beta * x_samp)</pre>
  # IS estimate (unbiased if we average p*w)
  est <- mean(p_vals * w)
  # Rough variance estimate
  \#p\_var \leftarrow mean((p\_vals * w)^2) - p\_hat^2
  #se <- sqrt(p_var / N)
  \#return(list(est = est, se = se, w_mean = mean(w)))
  return(list(est = est))
```

Results

5. Comparing Bias, Variance, and CPU Time for Simple MC, CV, and Importance Sampling

```
# 5.1. Obtain a "true value" via a large-scale Simple MC
set.seed(9999)
N_large <- 5e6

res_truth <- simpleMC(N_large)
true_value <- res_truth$est
# cat("Approx. True Value =", true_value, "\n")

# 5.2. Repeat simulations for smaller N and compare bias, variance
simulate_three_methods <- function(N, Eg_true) {
    # Simple MC</pre>
```

```
res_mc <- simpleMC(N)</pre>
  # CV
  res_cv <- cvMC(N, Eg_true = Eg_true)</pre>
  res_is <- IS_MC(N)</pre>
  c(mc = res_mc$est, cv = res_cv$est, is = res_is$est)
set.seed(1234)
N_reps <- 50
                     # number of repeated simulations
N_small <- 1e5  # sample size for each repeated run
# Pre-calculate Eg_true for CV (to avoid doing it multiple times)
Eg_val <- approx_Eg(N=5e5)</pre>
results_matrix <- replicate(N_reps, simulate_three_methods(N_small, Eg_true = Eg_val))
# results_matrix is now 3 x N_reps, each column is one replicate
mc_est <- results_matrix["mc", ]</pre>
cv_est <- results_matrix["cv", ]</pre>
is_est <- results_matrix["is", ]</pre>
# Compute mean estimate, bias, variance
mc_mean <- mean(mc_est)</pre>
cv_mean <- mean(cv_est)</pre>
is_mean <- mean(is_est)</pre>
mc_bias <- mc_mean - true_value</pre>
cv_bias <- cv_mean - true_value</pre>
is_bias <- is_mean - true_value
mc_var <- var(mc_est)</pre>
cv_var <- var(cv_est)</pre>
is_var <- var(is_est)</pre>
df_comparison <- data.frame(</pre>
  method = c("MC", "CV", "IS", "True"),
  mean_est = c(mc_mean, cv_mean, is_mean, true_value),
 bias = c(mc_bias, cv_bias, is_bias, NA),
  variance = c(mc_var, cv_var, is_var, NA)
# 5.3 Compare CPU time
test_time <- microbenchmark(</pre>
 MC = { simpleMC(N_small) },
  CV = { cvMC(N_small, Eg_true = Eg_val) },
 IS = { IS_MC(N_small) },
  times = 10  # repeat each method 10 times
```

Table 1: Estimated model mean, bias, and variance for each method using 100,000 samples; 'True' value is the MC result with 6,000,000 samples

Method	Estimated Mean	Bias	Variance
MC	0.7857719	-0.000144669	4.420e-07
CV	0.7857767	-0.000139931	8.000e-09
IS	0.7855314	-0.000385163	3.016e-06
True	0.7859166	NA	NA

Table 2: CPU time statistics (ms) for each method

Method	Min.	Lower Quartile	Mean	Median	Upper Quartile	Max.	# Eval
MC	13.82754	13.88695	13.97242	13.97096	14.04303	14.16177	10
CV	16.73058	16.81840	16.96688	16.93528	17.01980	17.40872	10
IS	34.99764	35.32298	36.15266	35.53464	35.71994	39.19174	10

Monte Carlo (MC) is the fastest because it only generates random samples and computes the mean, with O(N) complexity and no additional calculations.

Control Variates (CV) is slightly slower due to the extra step of computing a regression coefficient to reduce variance, but it improves estimation accuracy.

Importance Sampling (IS) is the slowest because it requires computing importance weights, normalizing them, and handling probability density functions, making it computationally more expensive (O(N log N) or higher).

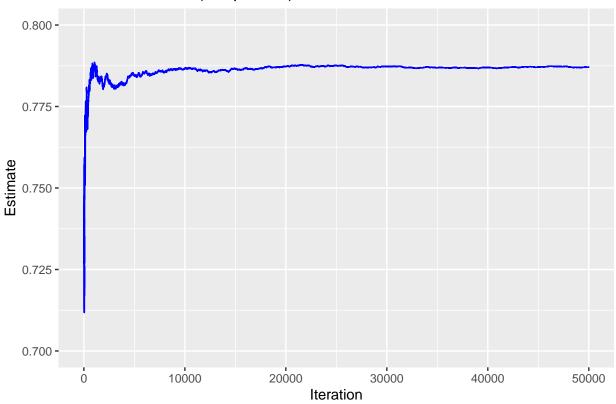

6. Cumulative Convergence Plots (Extra Credit)

Simple MC

```
# 6.1 Example of cumulative mean for Simple MC
cumulative_MC <- function(N) {</pre>
  b_{samp} \leftarrow r_b(N)
  x_{samp} \leftarrow r_x(N)
  p_vals <- logistic(alpha + b_samp + beta * x_samp)</pre>
  cum_mean <- cumsum(p_vals) / seq_len(N)</pre>
  return(cum_mean)
}
# 6.2 Plot cumulative mean
set.seed(999)
N \leftarrow 5e4
cm_mc <- cumulative_MC(N)</pre>
df_mc <- data.frame(</pre>
  iter = 1:N,
  mean est = cm mc
)
ggplot(df_mc, aes(x = iter, y = mean_est)) +
  geom_line(color = "blue") +
```

```
labs(title = "Cumulative Mean (Simple MC)",
    x = "Iteration",
    y = "Estimate") +
ylim(c(0.7, 0.8))
```

Cumulative Mean (Simple MC)

Control Variate Cumulative Mean

```
# This function returns a vector of CV estimates for i from 1 to N.
cumulative_CV <- function(N, Eg_true = NULL, largeN_approx = 5e5) {
   if (is.null(Eg_true)) {
